About This Test

Anti-HAV IgM refers to antibodies produced by the immune system in response to the Hepatitis A virus (HAV) during the acute phase of infection. IgM antibodies are the first immunoglobulins to appear in response to an infection and indicate recent or active HAV infection. The presence of Anti-HAV IgM antibodies in blood serum or plasma is detected using serological tests such as enzyme-linked immunosorbent assay (ELISA). This test helps diagnose acute hepatitis A, distinguish it from other types of viral hepatitis, and assess the stage of the disease. Anti-HAV IgM testing is crucial for confirming acute HAV infection, guiding public health interventions, and determining the need for further medical management or monitoring.
