About This Test

Rheumatoid factor (RF) qualitative test measures the presence of RF antibodies in the blood. RF is an autoantibody that targets the Fc region of IgG, a type of immunoglobulin. This test is primarily used to help diagnose rheumatoid arthritis (RA) and other autoimmune diseases. In patients with RA, the immune system mistakenl produces RF, which can form immune complexes and contribute to inflammation and joint damage. While a positive RF test can support the diagnosis of RA, it is not definitive, as RF can also be present in other conditions like Sjögren's syndrome, lupus, and chronic infections, and even in a small percentage of healthy individuals. The qualitative RF test simply indicates whether RF is present or absent in the blood, without providing a specific concentration. It is often used in conjunction with other clinic assessments and diagnostic tests to confirm a diagnosis and guide treatment decisions.
