About This Test

A Dengue IgG test measures the presence of IgG antibodies in the blood, which indicates a past infection with the dengue virus. IgG antibodies typically appear several weeks after the initial infection and remain in the body for years, providing long-term immunity. This test helps determine if a person has been previously exposed to the dengue virus, which is important for understanding immunity status and potential risk of future dengue infections. It is particularly useful in endemic areas for epidemiological studies and patient history assessment.
