About This Test

The H. pylori IgM antibodies test measures the presence of immunoglobulin M (IgM) antibodies specific to Helicobacter pylori in the blood. IgM is the first antibody produced in response to a new infection. This test helps detect a recent or active H. pylori infection. Elevated IgM levels suggest a current infection with H. pylori, which can cause conditions such as peptic ulcers or chronic gastritis. However, the IgM test is less commonly used than the IgG test for diagnosing H. pylori infections.
