About This Test

The Anti-HAV IgM test measures the presence of immunoglobulin M (IgM) antibodies specific to the hepatitis A virus (HAV) in the blood. These antibodies are produced by the immune system shortly after HAV infection and are indicative of an acute or recent hepatitis A infection. A positive result confirms a current or recent infection, whereas a negative result suggests the absence of a recent infection. This test is crucial for diagnosing hepatitis A, particularly in individuals presenting with symptoms such as jaundice, fatigue, abdominal pain, and elevated liver enzymes.
