About This Test

A **Bence-Jones protein** test measures the presence of abnormal proteins called Bence-Jones proteins in the urine. These proteins are produced by certain types of cancer cells, particularly plasma cells in multiple myeloma. Here's what the test assesses:

- Detection of Bence-Jones Proteins**: Identifies the presence of these abnormal proteins in the urine. Bence-Jones proteins are light chains of immunoglobulins (antibodies) that are produced in excess by malignant plasma cells.
- Diagnosis of Multiple Myeloma**: Helps in diagnosing multiple myeloma and related disorders, where these proteins are commonly found. It is often used in conjunction with other tests to confirm a diagnosis.
- Monitoring Disease Progression**: Used to monitor the progression of multiple myeloma or other plasma cell disorders and to evaluate the effectiveness of treatment.
- Kidney Function Assessment**: High levels of Bence-Jones proteins can lead to kidney damage, so the test also helps assess kidney function in patients with suspected or confirmed multiple myeloma.

In summary, a Bence-Jones protein test measures these abnormal proteins in the urine to help diagnose and manage multiple myeloma and other related disorders, as well as assess kidney function.
