About This Test

The Fat Globules (Stool) test is a laboratory examination used to detect the presence of fat particles in a stool sample. It helps evaluate how well the body digests and absorbs dietary fats. Normally, only a small amount of fat is present in stool, but increased fat globules may indicate a problem with digestion or absorption. This test is commonly recommended for individuals who have symptoms such as chronic diarrhea, greasy or foul-smelling stools, weight loss, abdominal discomfort, or signs of malnutrition. It is useful in identifying conditions related to malabsorption syndrome, pancreatic insufficiency, or intestinal disorders. A fresh stool sample is collected in a clean, dry container and examined under a microscope in the laboratory to identify fat globules. No fasting is required before the test. Proper sample collection is important to ensure accurate results and help in diagnosing digestive health issues effectively.
