About This Test

Rheumatoid factor (RF) measures the presence and levels of autoantibodies that target the Fc region of immunoglobulin G (IgG) in the blood. These autoantibodies are commonly associated with rheumatoid arthritis (RA) and can contribute to inflammation and joint damage by forming immune complexes. While a positive RF test support the diagnosis of RA, it is not exclusive to this condition and can be elevated in other autoimmune diseases such as Sjögren's syndrome and systemic lupus erythematosus as well as in chronic infections like hepatitis C and tuberculosis. A small percentage of healthy individuals, particularly the elderly, may also have elevated RF levels. RF testing includes both qualitative (presence/absence) and quantitative (concentration) assessments, which help in diagnosing RA, monitoring disease progression, and evaluating treatment response. However, due to its lack of specificity, RF results are typically considered alongside other clinical evaluations and diagnostic tests.
